Family Survivorship for Patients with Cancer: Existing Knowledge and Future Directions
Barbara Given, PhD, RN, FAAN
Michigan State University
University Distinguished Professor, College of Nursing

Charles Given, PhD
Michigan State University
Professor, College of Human Medicine, Department of Family Practice
Facts and Figures

- 10.5 million cancer survivors—therefore at least that many family members involved
- 66% of patients diagnosed today will be alive in 5 years—need family care
- 903,078 diagnosed this year—caregivers role over next 5 years
Survivorship Problems/Concerns – Patient

- Genetics/Health Practices
- Fertility/Sexuality
- Cognitive
- Dyadic Interaction - coping, communication, problem solving, decision making
- Employment/Insurance
- Uncertainty post treatment
- Economic hardships

All are relevant to the Family Caregiver
Survivorship and the Family

- Affects each family member

- Changes during treatment period: may or may not lead to changes in family roles & daily functioning during survivorship

- Affects family communication-family members want to move on-be done with cancer, patient can’t forget

- Fearful and uncertainty about future
What Survivor Caregivers do

- Who knows—sparse research except in palliative and end of life
- Serve as health advocates for patient
- Monitor patients follow-up
- Seek ways to return to “new normal”
- Maintain family
What Caregivers Are Required To Do

- Assume shared responsibilities for decisions/problem solving
- Monitor and manage symptoms and late side effects, detect early complications, deal with residual effects
- Monitor ongoing care and follow-up
- Receive little information assistance or guidelines from professionals
Knowledge About Caregiving During Treatment

- Risk factors for caregiver burden, distress and negative reaction
- Examined stress and coping
- Who cares and some content on tasks of care
- Rewards/gains occur from care – all care is not negative
- Not all caregivers are burdened or depressed, some caregivers do quite well
Caregivers Own Negative Emotional Effects into Survivorship

- Depression (20-30%)
- Coping and Adjustment
- Distress lasts beyond patient’s active treatment
- Unsure how these negative responses extend into survivorship
- Uncertainty
Stressors for Families in Care Situation

- Caregiver depression and burden are related to patient negative affective states
- Stable intensive care is not as stressful as is the distress from transition (whether improving or deteriorating)
- Change in the caregiver recipient/caregiver relationship—communication
- Regret with past decisions (caregiver or patient)
- Incongruence between reality and expectations of returning to normal
Stressors for Caregivers

- Uncertainty of future
- Decisional conflicts
- New late effects—new reaction and adjustment
- Residual effects or late effects (e.g. Lymphedema)
- Delay in patient return to function
- Interference with personal activities—want to return to new normal
- Safety Net gone
- Patient’s negative behaviors (Cognitive impairment and incontinence)
Economic Situation

- Employment and health insurance – caregivers change
- Financial debt may be altered long term
- Job re-engineering (caregiver)
- Out-of-pocket cost for long-term medications and other care
- Depletion of savings – also a late effect
Follow-up Care & Surveillance

- Own health care practices and family member health advocacy (Bowman)
- Little guidance on survivorship period-turned over to primary care
- Inconsistent follow-up care/no guidelines
- Emotional sequela unknown
- Compliance with lifelong or multi-agent therapeutic agents
- Relinquishing the caregiver role from treatment phase
Interventions

- No interventions found to address patient and caregiver transition into survivorship
- What type of interventions will facilitate transition and when should they be implemented?
- What change occurs in family structure, lifestyle modification and health promotion
- Does caregiver interventions during active treatment prevent caregiver distress in survivorship phase?
Survivorship Care Plan for Family Needed

- Summary of treatment and needed follow up
- Transitions to Primary Care
- Access to quality follow up care and surveillance
- Monitoring of late effects - menopausal, bone loss & osteoporosis, sexual problems, cardiovascular
- Insurability & employment (patient or caregiver)
- Education & information - tailored to situation
- Compliance with medications and follow-up
- Preventive practices and health promotion
- Rehabilitation and need for psychosocial services
Gaps in Knowledge – Future Research

- What is family role in survivorship phase?
- What is long-term impact on caregiver health of caregiving 5 to 10 years later?
- Is a successful caregiver during active therapy the successful caregiver in survivorship?
- Is the transition period shortened if the caregiver is a partner in care with the formal care system?
- How can caregivers influence patients transition into the survivorship phase?
- All knowledge and skills are not equal – ability to do physical care does not translate into transition care – what skills needed?
Gaps in Knowledge – Future Research

- How do minority, ethnic groups, and low-income caregivers respond to survivorship care?
- What mechanisms can be used to reach the overwhelmed caregivers transitioning – intervention trial?
- What role does caregiver have with primary care provider over survivorship plan of care?
- How do financial & economic sacrifices during treatment influence survivorship phase for caregivers?
- Does the proposed “family” survivorship plan of care work?
Gaps in Knowledge – Future Research

- What is the response of the caregiver to late effects?
- How does caregiver stress, burden or depression affect their decision-making and problem-solving involvement in care?
- What are the financial costs (informal) and opportunity costs to families?
- How does the impact on caregiver vary if major residual effects vs. new late effects?
Gaps in Knowledge – Future Research

- How does the quality of care during therapy affect the survivorship period?
- What patient outcomes during survivorship are most sensitive to family support?
- How can technology assist family caregiver in their care? (reduced distress,)(web, monitors, etc.)
- What is the OOP Cost of cancer care in the survivorship period?
- What are responses of non-spouses caregivers to continuing disability and late effects?
Gaps in Knowledge – Future Research

- How does life stage variation affect caregiver needs during survivorship (youth, young adult, adult, elderly)?

- What differences exist in caregiving when there are different family configurations (gay and lesbian, unmarried)?

- Will interventions targeted toward caregivers who are distressed, reduce distress during survivorship?

- What “type” of interventions are needed for caregiver transitions (information/education, psychoeducational etc)?
Gaps in Knowledge–Future Research

- Does early caregiver intervention targeted to transitions contribute positively to patient outcome?

- What is the relationship between informal care and patient long-term outcomes, e.g., symptom control, complications, functional return?
Family caregivers are a major resource - we need the science to understand how they contribute to the survivors care – and they need to be supported.

At the next 10 year celebration perhaps we can boldly say to “Who cares for the caregiver?”

“We all do.”
